

On some bilevel location and network design problems

Martine Labbé

Computer Science Department, Université Libre de Bruxelles & INOCS Team, INRIA, Lille, Belgium

A bilevel optimization problem consists in an optimization problem in which some of the constraints specify that a subset of variables must be an optimal solution to another optimization problem.

In this talk I will focus on some bilevel location and network design problems in which at the second level potential users decide to use the facility or travel on the network to optimize their own objective function which is different from that of first level.
